Sorting Lower Bound

Comparison-Based Sorting

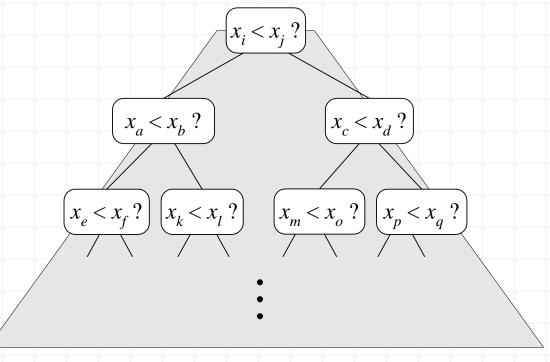

- Many sorting algorithms are comparison based.
 - They sort by making comparisons between pairs of objects
 - Examples: bubble-sort, selection-sort, insertion-sort, heap-sort, merge-sort, quick-sort, ...
- Let us therefore derive a lower bound on the running time of any algorithm that uses comparisons to sort n elements, x_1 , x_2 , ..., x_n .

Counting Comparisons

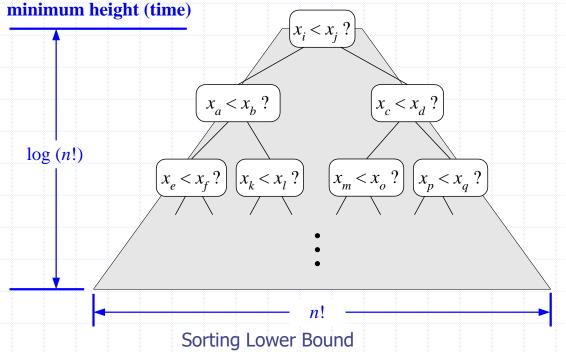

- Let us just count comparisons then.
- Each possible run of the algorithm corresponds to a root-to-leaf path in a decision tree

Decision Tree Height

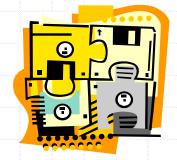

- The height of this decision tree is a lower bound on the running time
- Every possible input permutation must lead to a separate leaf output.
 - If not, some input ...4...5... would have same output ordering as ...5...4..., which would be wrong.

♦ Since there are n!=1*2*...*n leaves, the height is at least log (n!)

4

The Lower Bound

- Any comparison-based sorting algorithms takes at least log (n!) time
- Therefore, any such algorithm takes time at least

$$\log (n!) \ge \log \left(\frac{n}{2}\right)^{\frac{n}{2}} = (n/2)\log (n/2).$$

That is, any comparison-based sorting algorithm must run in $\Omega(n \log n)$ time.
